(Received 19 September 2001; accepted 13 May 2002; published 25 October 2002)

The refractive indices of 509 oxides and 55 fluorides were analyzed using two forms of a one-term Sellmeier equation: (1) $1/(n^2 - 1) = -A/\lambda^2 + B$, where A , the slope of the plot of $(n^2 - 1)^{-1}$ versus λ^{-2} in units of 10^{-16} m^2 , gives a measure of dispersion and B , the intercept of the plot at $\lambda = \infty$, gives $n_\infty = (1 + 1/B)^{1/2}$ and (2) $n^2 - 1 = E_d E_o / (E_o^2 - (\hbar\omega)^2)$, where $\hbar\omega$ = the photon energy, E_o = the average single oscillator (Sellmeier) energy gap, and E_d = the average oscillator strength, which measures the strength of interband optical transitions. Form (1) was used to calculate n at $\lambda = 589.3 \text{ nm}$ (n_D) and n at $\lambda = \infty$ (n_∞), and the dispersion constant A . The total mean polarizability for each compound was calculated using the Lorenz–Lorentz equation: $\alpha_e = 3/4\pi [(V_m)(n_\infty^2 - 1)/(n_\infty^2 + 2)]$, where V_m is the molar volume in \AA^3 . Provided for each compound are: n_D , n_∞ , V_m , $\langle \alpha_e \rangle$, $\langle A \rangle$, $\langle B \rangle$, $\langle E_d \rangle$, $\langle E_o \rangle$, the literature reference, the method of measurement of n and estimated errors in n . Results obtained by prism, infrared reflectivity, ellipsometry, and interference methods are compared. Consistency of dispersion values among like compounds and structural families is used to evaluate the accuracy of refractive index data. Dispersion values range from 40 to $260 \times 10^{-16} \text{ m}^2$ with the majority of values in the range of 60 – $100 \times 10^{-16} \text{ m}^2$. High dispersion is associated with s^2 , p^6 , d^{10} , and transition metal ions, H_2O , and crystalline hydrates, whereas normal dispersion values are found in borates, aluminates, gallates, silicates, germanates, phosphates, and sulfates not containing H_2O or any of the above ions. Exceptionally high dispersion is observed in liquid H_2O , Fe_2O_3 , $\text{Y}_3\text{Fe}_5\text{O}_{12}$, FeOOH , $\text{Fe}_2(\text{SO}_4)_3$, UO_2 , Cu_2O , V_2O_5 , $\text{MgCrO}_4 \cdot 7\text{H}_2\text{O}$, and $\text{Cs}_2\text{Mg}(\text{CrO}_4)_2 \cdot 6\text{H}_2\text{O}$. © 2002 American Institute of Physics. 1. Introduction

Refractive indices (n) and their dispersion are useful for the characterization of synthetic materials and minerals and for the prediction of linear and nonlinear refractive indices (n_2). Nonlinear refractive indices are defined by: $n = n_0 + n_2 \langle E^2 \rangle$ where n = observed refractive index at wavelength λ , n_0 = the linear refractive index, and E = the applied optical electric field [Adair *et al.* (1989)]. For example, nonlinear refractive indices of crystalline and glassy optical crystals have been related to linear refractive indices and their dispersion [Boling *et al.* (1978); Adair *et al.* (1989); Dimitrov and Sakka (1996)]. Also, in conjunction with dispersion studies and derived values of n_∞ , sets of empirical electronic ion polarizabilities α_e have been derived from (1) the Lorenz–Lorentz (LL) equation:

$$\alpha_e = 1/b[(V_m)(n_\infty^2 - 1)/(n_\infty^2 + 2)], \quad (1)$$

where V_m is the molar volume in \AA^3 , $b = 4\pi/3$ [Lorentz (1880); Lorenz (1880); Tessman *et al.* (1953); Kip (1962); Anderson (1974)] and n_∞ is the value of n extrapolated to infinite wavelength from a Sellmeier equation and (2) the additivity rule for the compound $M_2M'X_4$. The additivity rule states

$$\alpha_e(M_2M'X_4) = 2\alpha_e(M^{2+}) + \alpha_e(M'^{4+}) + 4\alpha_e(X^-), \quad (2)$$

where $\alpha_e(M_2M'X_4)$ is the total polarizability of the compound $M_2M'X_4$ and $\alpha_e(M^{2+})$, $\alpha_e(M'^{4+})$, and $\alpha_e(X^-)$ are the electronic polarizabilities of M^{2+} , M'^{4+} , and X^- , respectively. Using these relations, sets of ion polarizabilities were derived from data on the alkali halides and alkaline earth chalcogenides by Tessman *et al.* (1953); Pirenne and Kartheuser (1964); Wilson and Curtis, (1970); Boswarva (1970); Coker (1976); Raghurama and Narayan (1983); and from data on a variety of minerals by Lasaga and Cygan (1982).

During the course of the determination of an improved set of electronic polarizabilities, it was necessary to obtain a relatively complete database of refractive indices and dispersion over the visible part of the spectrum (400–700 nm). Although dispersion data such as those given in the compilations of Hintze (1897), (1933), (1938), (1960); Doelter (1914), (1917); Li (1980) and the Landolt-Börnstein (1962), (1969), (1979), (1981), (1996), (hereafter referred to as LB) series have been published, there was no central location for these data and it was frequently necessary to go to original publications to obtain dispersion data. Often there is no indication of the reliability of the data. In order to obtain n_∞ and dispersion constants, it is convenient to use Sellmeier analyses. Sellmeier constants have been provided for many compounds in these publications, but because of the large variety of Sellmeier equations [Tropf *et al.* (1995)], analysis using a common Sellmeier equation was not available.

To remedy this situation a literature search from the mid 1800s to the present was done to provide a relatively complete list of refractive indices and dispersion for minerals and synthetic fluorides and oxides (509 oxides and 55 fluorides). To be of use in the LL analysis, it is necessary that composition and unit cell volumes be available. Using the dispersion data and the one-term Sellmeier equation described by DiDomenico and Wemple (1969), we calculate dispersion parameters, the long-wavelength index n_∞ , and n_D , the index of refraction at the Na_D line. Using estimated experimental errors in n , comparisons of data on like compounds and trends in n and dispersion in structural families, we make a critical evaluation of the data. Finally, from the values of n_∞ , the unit cell volumes, and the LL equation, we calculate the total mean polarizability $\langle \alpha_e \rangle$ for each compound.

2. Presentation of Data

2.1. Composition, Characterization, and Source

This publication provides the composition, the refractive indices at $\lambda = \infty$ (n_∞), and 589.3 nm (n_D), molar volume of the compounds V_m , volume per anion V_o , total mean electronic polarizabilities $\langle \alpha_e \rangle$, the mean dispersion parameters $\langle A \rangle$, $\langle B \rangle$, $\langle E_o \rangle$, and $\langle E_d \rangle$, along with documentation providing an indication of the method of measuring n , the precision of the measurement of n , and source reference in an easily accessible form. Molar volume V_m is the unit cell volume divided by Z , the number of molecules per unit cell. Volume

per anion V_o is defined as the molar volume divided by the number of water molecules and anions ($H_2O + O^- + OH^- + F^-$). In the text the values of $\langle A \rangle$, $\langle B \rangle$, $\langle E_o \rangle$, and $\langle E_d \rangle$ for uniaxial and biaxial compounds, although written A , B , E_o , and E_d , are mean values. The compositions of synthetic compounds are generally accepted as correct. In the case of synthetic compounds, we give, when known, the crystal grower. Almost all of the data reported here are from single crystals. Exceptions are PLZT ($Pb-La-Zr-Ti-O_3$) compositions. In this case the data from $PbTiO_3$ ceramic with $n = 2.523$ ($\alpha_e = 9.668$) was found to compare well to single crystal data where one paper (Singh 1971) reported $n_o = 2.5218$ and $n_e = 2.5226$ ($\alpha_e = 9.665$) and another [Nomura *et al.* (1973)] $n = 2.5617$ ($\alpha_e = 9.792$). In those cases where single crystal data were not available, ceramic or polycrystalline sample is specified.

In the case of minerals we give the mineral name, the color, and where available, the source of the specimen. Mineral compositions are generally those given by the original author. Following the composition, the symbol * refers to well known compositions, either as-grown synthetic crystals or analyzed compositions of minerals. Many values of n and dispersion for oxides and minerals have been reported in the literature but we have only included those for which the unit cell is known and the composition is relatively certain. In some instances such as phenacite (Be_2SiO_4), even though no analysis was reported in the original papers, the data were included because of the high probability of the composition being correct. Many compositions, especially those reported in LB (1962), (1969), (1979), (1981), (1996); Hintze (1897), (1933), (1938), (1960); and Doelter (1914), (1917) are uncertain or questionable. In the case of the minerals, narsarsukite, leucosphenite, and sodalite, even though the analysis or unit cell dimensions are not well known, we have included the data because the refractive index was well determined. For these entries, we have used in parentheses the nominal or ideal compositions. In some cases, data from LB was omitted if the composition was uncertain and there were other examples available where the composition was known, e.g., garnets, cordierites, and beryls. In some instances such as for KH_2PO_4 , where a number of accurate determinations of n have been made, we have included only 1 or 2 of the more accurate measurements.

Finally, we give the source of the data. In many cases, we give the compilation from which the data were taken, e.g., Palik (1991); Hintze (1897), (1933), (1938), (1960); or Landolt-Börnstein (1962), (1969), (1979), (1981), (1996). When convenient, we give the original reference using the CASSI (Coden listed in the Chemical Abstracts Service Source Index) (1999). Appendix 1 lists the Codens used in this paper. The effective cutoff date for literature search is January 2000, whereas the earliest source was around 1850. Although Table 1 lists many of the dispersion data published between 1850 and 2000, it is not meant to be a complete tabulation. Overall, we present data for 509 oxides and 55 fluorides.

2.2. Method of Measuring Dispersion or n_∞

Although prism techniques have been used in the majority of dispersion determinations, a variety of other techniques have also been used. We include a code describing the method used to measure the refractive indices. The prism method using either minimum deviation or perpendicular incidence [Tilton (1935); Tilton *et al.* (1949); Werner (1968); Tentori and Lerma (1990); Medenbach and Shannon (1997); Medenbach *et al.* (2001)] has been used most often (about 60% of the data given here) and can give the refractive indices accurate to the fourth or fifth decimal place. The immersion method [Werner (1968); Verkouteren *et al.* (1992)] (about 10% of the data given here) is less accurate but can give values accurate to the 4th decimal place. Infrared reflectivity (IR) measurements in conjunction with Kramers-Kronig analysis or the Lorentz oscillator model and classical dispersion theory [Barker (1964)] give the long wavelength dielectric constant, $\epsilon_\infty = n_\infty^2$, from fitting the parameter ϵ_∞ to the reflectivity data. In general, data obtained in this manner (about 10% of the data given here) are accurate to the third decimal place. Some papers use an independent measurement of n_∞ and it is not always possible to distinguish these values from the fitted values. When both IR and minimum deviation measurements have been made, they have both been tabulated for comparison. Ellipsometer methods [Jellison (1997); Jellison and Modine (1997)] have been used more recently and give results somewhat less accurate than prism methods. We have compared several sets of data using both ellipsometer and prism methods and find agreement to ± 0.02 – 0.05 . Critical angle methods including the use of the Abbe-Pulfrich refractometer [Straat and Forrest (1939); Tilton (1942, 1943); Hurlbut (1984)] have been used often but not in determining dispersion. Finally, interference methods using a Michelson-type interferometer have also been used for determining dispersion [Grehn (1959); Werner (1968); Moskalev and Smirnova (1987); Shumate (1966)]. The method of measuring n is not always given. Values quoted to four decimal places in LB were assumed to be obtained by prism methods and therefore to be accurate to ± 0.0001 – 0.0005 , except when indicated otherwise.

2.3. Sellmeier Analysis

There are many dispersion formulas that have been developed to fit the refractive index over a wide range of frequencies. Many of the most common formulas are described by Tropf *et al.* (1995). However, the single-term Sellmeier equation used by DiDomenico and Wemple (1969) and Wemple and DiDomenico (1971) has the advantages of simplicity and of providing derived parameters that have physical significance. In the form

$$1/(n^2 - 1) = -A/\lambda^2 + B, \quad (3a)$$

A , the slope of the plot of $(n^2 - 1)^{-1}$ versus λ^{-2} in units of 10^{-16} m^2 gives a measure of dispersion and B , the intercept

TABLE I. Refractive index and dispersion data, listing refractive indices (n_x , n_y , n_z) at $\lambda = \infty$, refractive indices (n_{Dx} , n_{Dy} , n_{Dz}) at $\lambda = 589.3$ nm, molar volume, V_m , volume per O atom, V_o , and mean values of electronic polarizabilities ($\langle a_e \rangle$), mean dispersion values ($\langle A \rangle$ and $\langle B \rangle$) according to Eq. (3a), and average of E_o and E_d according to Eq. (3b). Source references use Codens from the American Chemical Society, Chemical Abstracts Service Source Index 1907-1999 Cumulative (American Chemical Society, Washington, DC, 2000). (Symbols * and + and numerical values for method and error can be found at the end of the table.)

TABLE I. Refractive index and dispersion data, listing refractive indices (n_x , n_y , n_z) at $\lambda = \infty$, refractive indices (n_{Dx} , n_{Dy} , n_{Dz}) at $\lambda = 589.3$ nm, molar volume, V_m , volume per O atom, V_o , and mean values of electronic polarizabilities ($\langle \alpha_e \rangle$), mean dispersion values ($\langle A \rangle$ and $\langle B \rangle$) according to Eq. (3a), and average of E_o and E_d according to Eq. (3b). Source references use Codens from the American Chemical Society, Chemical Abstracts Service Source Index 1907-1999 Cumulative (American Chemical Society, Washington, DC, 2000). (Symbols * and + and numerical values for method and error can be found at the end of the table.)—Continued

TABLE I. Refractive index and dispersion data, listing refractive indices (n_x , n_y , n_z) at $\lambda = \infty$, refractive indices (n_{Dx} , n_{Dy} , n_{Dz}) at $\lambda = 589.3$ nm, molar volume, V_m , volume per O atom, V_o , and mean values of electronic polarizabilities (α_e), mean dispersion values ($\langle A \rangle$ and $\langle B \rangle$) according to Eq. (3a), and average of E_o and E_d according to Eq. (3b). Source references use Codens from the American Chemical Society, Chemical Abstracts Service Source Index 1907-1999 Cumulative (American Chemical Society, Washington, DC, 2000). (Symbols * and + and numerical values for method and error can be found at the end of the table.)—Continued

TABLE I. Refractive index and dispersion data, listing refractive indices (n_x , n_y , n_z) at $\lambda = \infty$, refractive indices (n_{Dx} , n_{Dy} , n_{Dz}) at $\lambda = 589.3$ nm, molar volume, V_m , volume per O atom, V_o , and mean values of electronic polarizabilities ($\langle a_e \rangle$), mean dispersion values ($\langle A \rangle$ and $\langle B \rangle$) according to Eq. (3a), and average of E_o and E_d according to Eq. (3b). Source references use Codens from the American Chemical Society, Chemical Abstracts Service Source Index 1907–1999 Cumulative (American Chemical Society, Washington, DC, 2000). (Symbols * and + and numerical values for method and error can be found at the end of the table.)—Continued

TABLE I. Refractive index and dispersion data, listing refractive indices (n_x , n_y , n_z) at $\lambda = \infty$, refractive indices (n_{Dx} , n_{Dy} , n_{Dz}) at $\lambda = 589.3$ nm, molar volume, V_m , volume per O atom, V_o , and mean values of electronic polarizabilities ($\langle e_e \rangle$), mean dispersion values ($\langle A \rangle$ and $\langle B \rangle$) according to Eq. (3a), and average of E_O and E_d according to Eq. (3b). Source references use Codens from the American Chemical Society, Chemical Abstracts Service Source Index 1907–1999 Cumulative (American Chemical Society, Washington, DC, 2000). (Symbols * and + and numerical values for method and error can be found at the end of the table.)—Continued

REFRACTIVE INDEX AND DISPERSION

TABLE I. Refractive index and dispersion data, listing refractive indices (n_x , n_y , n_z) at $\lambda = \infty$, refractive indices (n_{Dx} , n_{Dy} , n_{Dz}) at $\lambda = 589.3$ nm, molar volume, V_m , volume per O atom, V_o , and mean values of electronic polarizabilities ($\langle \alpha_e \rangle$), mean dispersion values ($\langle A \rangle$ and $\langle B \rangle$) according to Eq. (3a), and average of E_o and E_d according to Eq. (3b). Source references use Codens from the American Chemical Society, Chemical Abstracts Service Source Index 1907–1999 Cumulative (American Chemical Society, Washington, DC, 2000). (Symbols * and + and numerical values for method and error can be found at the end of the table.)—Continued

TABLE I. Refractive index and dispersion data, listing refractive indices (n_x , n_y , n_z) at $\lambda = \infty$, refractive indices (n_{Dx} , n_{Dy} , n_{Dz}) at $\lambda = 589.3$ nm, molar volume, V_m , volume per O atom, V_o , and mean values of electronic polarizabilities (α_e), mean dispersion values ($\langle A \rangle$ and $\langle B \rangle$) according to Eq. (3a), and average of E_o and E_d according to Eq. (3b). Source references use Codens from the American Chemical Society, Chemical Abstracts Service Source Index 1907–1999 Cumulative (American Chemical Society, Washington, DC, 2000). (Symbols * and + and numerical values for method and error can be found at the end of the table.)—Continued

TABLE I. Refractive index and dispersion data, listing refractive indices (n_x , n_y , n_z) at $\lambda = \infty$, refractive indices (n_{Dx} , n_{Dy} , n_{Dz}) at $\lambda = 589.3$ nm, molar volume, V_m , volume per O atom, V_o , and mean values of electronic polarizabilities (α_e), mean dispersion values ($\langle A \rangle$ and $\langle B \rangle$) according to Eq. (3a), and average of E_o and E_d according to Eq. (3b). Source references use Codens from the American Chemical Society, Chemical Abstracts Service Source Index 1907-1999 Cumulative (American Chemical Society, Washington, DC, 2000). (Symbols * and + and numerical values for method and error can be found at the end of the table.)—Continued

TABLE I. Refractive index and dispersion data, listing refractive indices (n_x , n_y , n_z) at $\lambda = \infty$, refractive indices (n_{Dx} , n_{Dy} , n_{Dz}) at $\lambda = 589.3$ nm, molar volume, V_m , volume per O-atom, V_O , and mean values of electronic polarizabilities ($\langle \alpha_e \rangle$), mean dispersion values ($\langle A \rangle$ and $\langle B \rangle$) according to Eq. (3a), and average of E_O and E_d according to Eq. (3b). Source references use Codens from the American Chemical Society, Chemical Abstracts Service Source Index 1907-1999 Cumulative (American Chemical Society, Washington, DC, 2000). (Symbols * and + and numerical values for method and error can be found at the end of the table.)—Continued

TABLE I. Refractive index and dispersion data, listing refractive indices (n_x , n_y , n_z) at $\lambda = \infty$, refractive indices (n_{Dx} , n_{Dy} , n_{Dz}) at $\lambda = 589.3$ nm, molar volume, V_m , volume per O atom, V_o , and mean values of electronic polarizabilities (α_e), mean dispersion values ($\langle A \rangle$ and $\langle B \rangle$) according to Eq. (3a), and average of E_o and E_d according to Eq. (3b). Source references use Codens from the American Chemical Society, Chemical Abstracts Service Source Index 1907-1999 Cumulative (American Chemical Society, Washington, DC, 2000). (Symbols * and + and numerical values for method and error can be found at the end of the table.)—Continued

TABLE I. Refractive index and dispersion data, listing refractive indices (n_x , n_y , n_z) at $\lambda = \infty$, refractive indices (n_{Dx} , n_{Dy} , n_{Dz}) at $\lambda = 589.3$ nm, molar volume, V_m , volume per O-atom, V_o , and mean values of electronic polarizabilities ($\langle \alpha_e \rangle$), mean dispersion values ($\langle A \rangle$ and $\langle B \rangle$) according to Eq. (3a), and average of E_o and E_d according to Eq. (3b). Source references use Codens from the American Chemical Society, Chemical Abstracts Service Source Index 1907-1999 Cumulative (American Chemical Society, Washington, DC, 2000). (Symbols * and + and numerical values for method and error can be found at the end of the table.)—Continued

^aBoldfaced values refer to discrepancies greater than experimental values.

of the plot at $\lambda=\infty$, gives $n_\infty=(1+1/B)^{1/2}$. In Appendix 2, we give alternative forms of this equation. The n_∞ values derived from Eq. (3a) are necessary for the correct application of the Lorenz–Lorentz relation to obtain ion polarizabilities. The values of n_∞ derived in this paper from one-term Sellmeier analyses of data from the visible region results in n_∞ that comes only from electronic transitions. This n_∞ is distinctly different from the dielectric n_∞ derived from the dielectric constant $\epsilon_o=n_\infty^2$, obtained in the kHz–MHz region where both lattice vibrations and electronic transitions contribute to the dielectric constant. This is shown graphically by Tropf *et al.* (1995) in their Fig. 1, p. 33.13 and is illustrated numerically by the value of refractive indices of quartz

where from optical data, $\langle n_\infty \rangle=1.547$, and from dielectric constant data at 1 kHz, $\langle n_\infty \rangle=2.135$ (Shannon, 1993).

An alternative form [Wemple and DiDomenico (1971); Wemple (1973, 1977)] is

$$n^2 - 1 = E_d E_o / (E_o^2 - (\hbar\omega)^2), \quad (3b)$$

where in a single oscillator model $\hbar\omega$ =the photon energy, E_o =the average single oscillator (Sellmeier) energy gap in eV, and E_d =the average oscillator strength in eV, which measures the average strength of interband optical transitions and E_d is related to physical parameters by the expression $E_d=\beta N_c Z_a N_e$, where N_c is the cation coordination number, Z_a is the formal valence of the anion, N_e is the effective

^aAccuracy index defined in Table 1.

number of valence electrons/anion, $\beta=0.26$ for ionic compounds, and $\beta=0.37$ for covalent compounds. These parameters were analyzed for more than 100 compounds by Wemple and DiDomenico (1971). The scheme was found to work well for simple single-bond halides and oxides as well as a number of more complex multibond oxides containing two cations of differing coordination. However, it was necessary to assume covalent character ($\beta=0.37$) for scheelite-type molybdates and tungstates and several iodates and carbonates. In this paper we consider both single-bond and multibond oxides and fluorides.

In general, dispersion parameters are not identical for light polarized along the different axes of uniaxial and biaxial crystals. This results in dispersion parameters that vary with the crystal orientation. However, for simplicity in the tables, we list only mean values of $\langle A \rangle$, $\langle B \rangle$, $\langle E_o \rangle$, and $\langle E_d \rangle$. In the text following, although we omit the brackets, all values of A , B , E_o , and E_d are understood to be mean values.

When numerical values were given, we have used those data to determine the one-term Sellmeier parameters [Eq.

(3a)]. When data were presented in the form of different Sellmeier equations, we used the equations to calculate numerical dispersion data for use in Eq. (3a) and when data were provided only in graphical form, the dispersion data were taken from these plots.

2.4. Error Limits

Where possible, we have given error limits as reported; when no error limits were reported, we have either stated that or estimated the errors. Following the composition, the symbol + refers to compounds with the most reliable refractive indices, generally with $\delta n = \pm 0.0001\text{--}0.0005$. When refractive indices are quoted to four decimal places in Landolt-Börnstein, as for example for the many sulfates studied by Tutton over the years 1890–1930, we have assumed error limits of $\pm 0.0001\text{--}0.0005$. Estimated error limits are only valid for the refractive index and do not take errors in composition into consideration. Crystals studied before the early

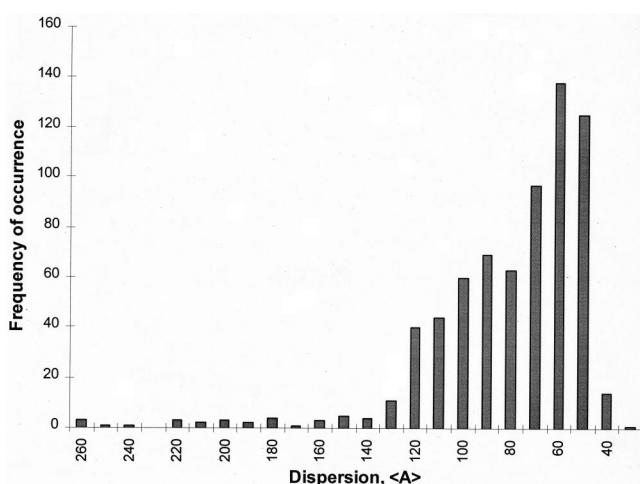

FIG. 1. Mean dispersion value $\langle A \rangle$ vs frequency of occurrence.

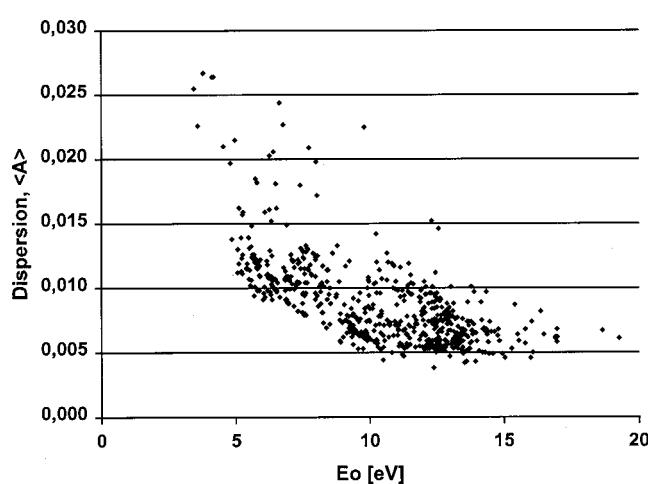

FIG. 2. Dispersion A vs average Sellmeier energy gap E_o .

1900s and for which four significant figures are quoted in the original papers are assumed to be measured by prism methods.

3. Results and Discussion

Table 1 provides 73 measurements on 55 fluorides, 9 measurements on chlorides, and 750 measurements on 509 oxides. In the table we give the specimen composition and source, the refractive indices at $\lambda = \infty$ and 589.3 nm, molar volume V_m , volume per anion V_o , electronic polarizabilities α_e , the mean dispersion parameters, A , B , E_o , and E_d , along with indices that provide an indication of the method of measuring n , the estimated error in n , the reliability of the composition and refractive index data, and source reference in an easily accessible form.

3.1. Comparison of Data Using Different Methods

In Table 2 we compare the results of determinations of n_∞ by prism, IR, ellipsometer, and interference methods. In general, results obtained for prism or interference and IR methods are identical within experimental error. Exceptions are PbF_2 , RbMnF_3 , Cu_2O , EuO , GeO_2 , ThO_2 , UO_2 , and $\text{PbMg}_{0.33}\text{Nb}_{0.67}\text{O}_3$, as noted by boldfaced values in Table 2. The discrepancy in $n_\infty(\text{PbF}_2)$ was noted by Axe *et al.* (1965) and attributed to an inadequacy of the Lyddane-Sachs-

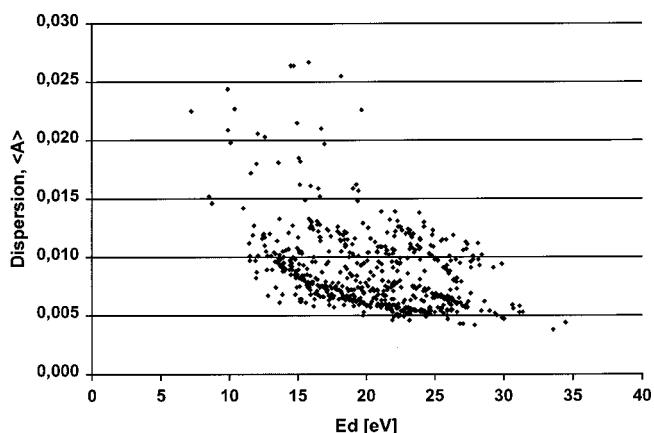

FIG. 3. Dispersion A vs average oscillator strength.

Teller (LST) relation. Similarly, the high value for $n_\infty(\text{RbMnF}_3)$ was noted by Perry and Young (1967). The three IR values of $n_\infty(\text{Cu}_2\text{O}) = 2.54$, 2.55, and 2.57, obtained from the IR measurements, agree reasonably well and are probably more accurate than the value of $n_\infty(\text{Cu}_2\text{O}) = 2.27$ obtained from prism data in LB. This value derived from data determined in 1871 appears systematically low compared with the IR values and the 643.8 nm value of 2.89 determined by Medenbach and Shannon (1997).

^cBoldfaced values of $\langle E_o \rangle$ and $\langle E_d \rangle$ are relatively low.

There is a large discrepancy between the EuO prism value of $n=1.96$ quoted by Wachter (1968) and the IR value of 2.30 from Axe (1969). An alternative method of deciding which of these is more correct is to use the data from $\beta\text{-Eu}_2\text{SiO}_4$ along with the additivity rule [Eq. (2)] where the total polarizability $\alpha_e(\beta\text{-Eu}_2\text{SiO}_4)$ is 10.19 Å^3 (see Table 1). Subtracting $\alpha_e(\text{SiO}_2)=2.803 \text{ Å}^3$, we arrive at $\alpha_e(\text{EuO})=3.69 \text{ Å}^3$, which corresponds to $n_\infty=1.87$, much closer to the prism value $n_\infty=1.96$ than the IR value.

The large discrepancy between prism and IR data from GeO_2 is probably caused by poor data or IR analysis. This is evident from the $n_\infty(\text{GeO}_2)$ IR values of $n_o=2.02$ and $n_e=2.10$, which are improbably larger than $n_\infty(\text{SnO}_2)$ prism values of $n_o=1.9442$ and $n_e=2.0449$. The IR values of $n_\infty(\text{ThO}_2)=2.20$ and $n_\infty(\text{UO}_2)=2.33$ by Axe and Pettit (1966) are significantly larger than the value of 2.070 obtained by Ellis and Lindstrom (1964) for ThO_2 and the UO_2 value of 2.16 by Ellis (1964) using prism methods. Axe and Pettit noted this fact and attributed the discrepancy to an inadequacy of the LST relation. The final example of the deviation of IR results from prism methods concerning $\text{PbMg}_{0.33}\text{Nb}_{0.67}\text{O}_3$ where IR data give 2.49 (Karamyan, 1976) and prism method results in a value of $n_\infty=2.422$ (Kamzina, 1974). Here the results may be within experimental error since the errors were not given.

3.2. Comparison of Dispersion Values

An independent method of checking accuracy is to compare dispersion constants A with values from like compounds and from trends in structural families. The value of A is perhaps as sensitive a test for accuracy as estimated errors in n . Table 3 shows a number of examples of inconsistencies

in A . Some examples of like-compound discrepancies are Cs_2SiF_6 , Cs_2GeF_6 , Y_2O_3 , SiO_2 , TiO_2 , BaMgF_4 , Zn_2SiO_4 , Mn_2SiO_4 , $\text{Y}_3\text{Ga}_5\text{O}_{12}$, $\text{Ca}_3\text{Al}_2\text{Si}_3\text{O}_{12}$, CaTiSiO_5 , YVO_4 , CaMoO_4 , PbWO_4 , and $\text{KAl}(\text{SO}_4)_2 \cdot 12 \text{ H}_2\text{O}$. Examples of deviations from structural family trends are Na_2GeF_6 in the M_2GeF_6 family ($\text{M}=\text{Na}, \text{Rb}, \text{Cs}$), $\text{Y}_3\text{Ga}_5\text{O}_{12}$ in the $\text{M}_3\text{Ga}_5\text{O}_{12}$ garnet family ($\text{M}=\text{Y}, \text{Nd}, \text{Dy}, \text{Ho}, \text{Tm}$), $\text{Ba}_{0.75}\text{Sr}_{0.25}\text{Nb}_2\text{O}_6$ in the $\text{Ba}_{1-x}\text{Sr}_x\text{Nb}_2\text{O}_6$ family, $\text{Tl}_2\text{Ni}(\text{SO}_4)_2 \cdot 6 \text{ H}_2\text{O}$ in the $\text{Tl}_2\text{M}(\text{SO}_4)_2 \cdot 6 \text{ H}_2\text{O}$ family ($\text{M}=\text{Fe}, \text{Co}, \text{Cu}, \text{Ni}$), and $\text{KAl}(\text{SO}_4)_2 \cdot 12 \text{ H}_2\text{O}$ in the alum family $\text{MAl}(\text{SO}_4)_2 \cdot 12 \text{ H}_2\text{O}$ ($\text{M}=\text{K}, \text{Rb}$). The samples which show values differing substantially from the values in like compounds and values shown in family trends have been marked in Table 1 with a question mark following the accuracy index, as defined in Table 1.

In the example of Y_2O_3 , the value of $A=75 \times 10^{-16} \text{ m}^2$ is consistent with accurate RE_2O_3 values from Sc_2O_3 ($66 \times 10^{-16} \text{ m}^2$), Lu_2O_3 ($66 \times 10^{-16} \text{ m}^2$), Yb_2O_3 ($68–69 \times 10^{-16} \text{ m}^2$), and Dy_2O_3 ($73 \times 10^{-16} \text{ m}^2$). The measurements for the outliers Y_2O_3 of 125 , 62 , and $53 \times 10^{-16} \text{ m}^2$ probably resulted from systematic errors that influence A more than n_∞ . The dispersion parameter A for $\text{Y}_{0.95}\text{Tm}_{0.05}\text{VO}_4$ of $164 \times 10^{-16} \text{ m}^2$ [Ohta *et al.* (1993)] seems high in light of the values of 109 and $102 \times 10^{-16} \text{ m}^2$ for YVO_4 [Kuwano and Saito (1990); Medenbach and Shannon (1997)] and $98 \times 10^{-16} \text{ m}^2$ for $\text{Y}_{0.98}\text{Nd}_{0.02}\text{VO}_4$ [Lonheim and DeShazer (1978)]. Similarly, the dispersion value for $\text{Ba}_{0.75}\text{Sr}_{0.25}\text{Nb}_2\text{O}_6$ of $79 \times 10^{-16} \text{ m}^2$ seems inconsistently lower than the values of $102–93 \times 10^{-16} \text{ m}^2$ observed for other members of the family $\text{Ba}_{1-x}\text{Sr}_x\text{Nb}_2\text{O}_6$. The value 79 was derived from only two values of n at 633 and 1050 nm [Venturini *et al.* (1968)]; the value at 1050 nm is perhaps out of range of validity for the Sellmeier equation. Dispersion from eight samples of ti-

tanite with a nominal composition CaTiSiO_5 showed an unusually large variation with values ranging from 73 to $120 \times 10^{-16} \text{ m}^2$. This is perhaps not surprising in light of the presence of twinning in most samples and a variation in composition with analyzed compositions ranging from $\text{Ca}_{0.75}\text{Ti}_{1.05}\text{Si}_{1.07}\text{O}_5$ to $\text{Ca}_{1.0}\text{Ti}_{0.98}\text{Mn}_{0.05}\text{Si}_{0.99}\text{O}_5$ [Hintze (1897)]. However, we have judged the values of 73 and 91 in CaTiSiO_5 from Eisbruckalp in Pfunders, Tirol and Glimmerschiefer in St. Gotthard to be lower than expected for titanites.

Although many of the outliers, such as Cs_2SiF_6 , Cs_2GeF_6 , RbH_2PO_4 , Mn_2SiO_4 , PbWO_4 , $\text{Gd}_3\text{Sc}_2\text{Al}_3\text{O}_{12}$, and CaTiSiO_5 have lower reported accuracies, others were reported to have good accuracy, i.e., $\delta n = \pm 0.0001$ –0.0005. Although the dispersion value for CaTiO_3 ($127 \times 10^{-16} \text{ m}^2$) quoted from Driscoll and Vaughn⁷ (Table 1) is consistent with the values of A from SrTiO_3 and BaTiO_3 , the values of n_∞ of 1.5554 and 1.3304 are far too low. The value of n_∞ of 2.261 obtained using the Chaulnes method by Linz and Herrington (1958) is more reasonable, suggesting either a calculation error or that the value obtained by Driscoll and Vaughn⁷ was from a compound other than CaTiO_3 .

3.3. Analysis of Dispersion Values

Dispersion values A range from ~ 40 to $260 \times 10^{-16} \text{ m}^2$. Their distribution is shown in Fig. 1. The largest number of values is centered around $60 \times 10^{-16} \text{ m}^2$ with a second distribution centered around 90 – $100 \times 10^{-16} \text{ m}^2$ and much smaller numbers distributed over the range 140 – $250 \times 10^{-16} \text{ m}^2$. For convenience we arbitrarily call the range from 50 to 80 “normal dispersion,” and 80 to 250 “high dispersion.” In this section we make an effort to rationalize the high dispersion values A . As a framework for the analysis of dispersion parameters, we use the analysis of Wemple and DiDomenico (1971) and Wemple (1977). In this scheme A is proportional to $1/E_o E_d$, where E_o =the average single oscillator energy and E_d =the oscillator strength which measures the average strength of interband optical transitions. According to DiDomenico and Wemple (1971), E_d is related to physical parameters by the expression

$$E_d = \beta N_c Z_a N_e, \quad (4)$$

where N_c is the cation coordination number, Z_a is the formal valence of the anion, N_e is the effective number of valence electrons/anion, $\beta=0.26$ for ionic compounds, and $\beta=0.37$ for covalent compounds. Using this scheme high dispersion values should result for compounds with:

- (1) low energy gaps,
- (2) ionic character,
- (3) cations having low N_c ,
- (4) fluoride rather than oxide anions; and
- (5) cations with low N_e .

DiDomenico and Wemple (1969) and Wemple (1977) concentrated primarily on optical dielectric constants (refractive indices) and their relationships to the above variables but they were not concerned specifically with dispersion, although DiDomenico and Wemple (1969) noted that the refractive index dispersion is approximately inversely related to the average single oscillator Sellmeier gap E_o . In this section we focus primarily on the dispersion A and the relationship to chemical composition and electron configuration of the atoms involved and find that many of the trends in A can be explained by the above five factors. Wemple and DiDomenico (1971) and Wemple (1977) showed that low values of E_o are associated with the d^{10} cations Cu^+ and Ag^+ , and the s^2 cations As^{3+} , Te^{4+} , I^{5+} , Tl^+ , Pb^{2+} , and Bi^{3+} .

Figures 2 and 3 show plots of A vs E_o and A vs E_d , respectively. The plot of A vs E_o shows a better fit to $1/E_o$ than $1/E_d$ which we interpret to mean that variations in E_o are more important in explaining dispersion than variations in E_d . We shall analyze this assumption in Secs. 3.3.1–3.3.5. A survey of the dispersion parameters of the compounds in Table 1 shows high dispersion values A associated with certain ions which we call “soft” ions, i.e., s^2 , p^6 , d^{10} and transition metal ions, H_2O , and crystalline hydrates. In Tables 4–8 we have listed the dispersion parameters A , E_o , and E_d of compounds containing s^2 , p^6 , d^{10} , and transition metal ions. Normal values of dispersion ($A=50$ – $80 \times 10^{-16} \text{ m}^2$) were found in borates, aluminates, gallates, silicates, germanates, phosphates, and sulfates not containing

^aAtom % = (total "soft ions" + H₂O)/(total cations + anions).^bBoldfaced values of $\langle A \rangle$ are relatively high.^cBoldfaced values of $\langle E_o \rangle$ and $\langle E_d \rangle$ are relatively low.

any of the above "soft" ions. It appears that A depends on the total concentration of "soft" ions where these ions must be in concentrations >10%–15%. This number seems to depend on the ion, being lower for Fe³⁺, Co²⁺, Ti⁴⁺, and Bi³⁺, and higher for Zn²⁺, Nb⁵⁺, Ta⁵⁺, Tl⁺, and Pb²⁺. In Tables 4–9 values of $\langle A \rangle$ in boldface type are relatively high, whereas boldface values of $\langle E_o \rangle$ and $\langle E_d \rangle$ are relatively low.

3.3.1. Transition Metal Ions

Table 4 shows that many of the compounds containing the transition metal ions Fe³⁺, Co²⁺, Ni²⁺, Eu²⁺, and U⁴⁺ with $A = 150–265$ have some of the highest dispersion values of all oxides. Fe₂O₃ (hematite), FeOOH (lepidocrocite), and Fe₂(SO₄)₃ all have dispersion values greater than $200 \times 10^{-16} \text{ m}^2$. The high dispersion values in transition metal

^aAtom % = (total “soft ions” + H₂O)/(total cations + anions).^bBoldfaced values of $\langle A \rangle$ are relatively high.^cBoldfaced values of $\langle E_o \rangle$ and $\langle E_d \rangle$ are relatively low.

oxides correlate well with values of the parameter E_o (4–8 eV) and, in general, low values of the parameter E_d . Even with relatively low concentrations (10%) of Fe³⁺ rather high dispersion values result. Note that although there is only 4 at % of Fe in MFe(SO₄)₂ · 12 H₂O and 8% in cornellite, Fe₂(SO₄)₃ · 7 H₂O, the total concentrations of “soft” ions (Fe³⁺) and H₂O are 54% and 37%, respectively. Similarly, in MCr(SO₄)₂ · 12 H₂O, both Cr³⁺ and H₂O contribute to the dispersion. It is apparently not necessary for the ions to be linked, e.g., compounds with isolated Fe³⁺ such as Ca₃Fe₂Si₃O₁₂, Na_{0.87}Fe_{0.92}Al_{0.05}Ti_{0.03}Si₂O₆ (aegirine), and M₂CoSi₂O₇ (M=Ca, Sr) have high dispersion (A = 100–175). Hydrates such as FeSO₄OH · 2 H₂O and MFe(SO₄)₂ · 2 H₂O (M=K, Rb, Cs and Tl) have higher val-

ues of E_o (8–10 eV) but because of low E_d (12–13 eV) as for other hydrates (see below) still show high dispersion.

3.3.2. d¹⁰ Ions

Table 5 shows the dispersion parameters for compounds containing Cu⁺, Zn²⁺, As⁵⁺, and I⁷⁺. Among the oxides Cu₂O has one of the highest dispersions (A = 267), apparently because of the exceptionally low energy gap of 3.8 eV. Among the Zn-containing compounds only ZnO (A = 159–185) and ZnWO₄ (A = 82–86) have high dispersion. ZnO has both low E_o and E_d (CN=IV), whereas ZnWO₄ has low E_o but a higher E_d caused by CN=6 for both Zn and W. Note that the high dispersion of ZnWO₄ results from the

^aBoldfaced values of $\langle A \rangle$ are relatively high.

^bBoldfaced values of $\langle E_o \rangle$ and $\langle E_d \rangle$ are relatively low.

combined presence of Zn^{2+} and W^{6+} . All the other Zn-containing compounds have relatively high oscillator energies and therefore lower dispersion. Arsenates which might be expected to have low dispersion because of their high E_o have relatively high dispersion resulting from tetrahedral As^{5+} and low E_d . KIO_4 , the only example of an iodate, has high dispersion ($A=133$) because of both low E_o and E_d (CN=IV for I^{7+}).

3.3.3. p^6 Ions

In Table 6 we list the dispersion parameters for titanates, vanadates, chromates, niobates, tantalates, molybdates, and tungstates. All titanium-bearing compounds with $>10\%$ Ti content have high dispersion, and are associated with E_o values in the range of 5–8 eV. Between 12% and 33% Ti there is no obvious concentration dependence. Fresnoite, $\text{Ba}_2\text{TiSi}_2\text{O}_8$, the one Ti compound with Ti<10% has normal dispersion.

Similarly all vanadates have high dispersion values with V_2O_5 having one of the highest values ($A=264$) and one of lowest values of $E_o=4.1$ eV. Values of the vanadate parameter E_o are similar to those of the titanates, being in the range 4–8 eV. Although chromate dispersions are augmented by the presence of H_2O (see below), we believe because of the exceptionally high values of A , the primary contributor to the high dispersion is the presence of the Cr^{6+} ion. Most niobates and tantalates have high dispersion but the values depend on the concentration with significantly lower dispersion for $\text{Ba}_3\text{LaNb}_3\text{O}_{12}$ and LaNbO_4 , where E_o has increased to 8.4 eV. Tantalates, because of slightly higher E_o values, have slightly lower dispersion than niobates, e.g., compare LiNbO_3 with $A=91–88$ and LiTaO_3 with $A=81–79$. All reported molybdates have high dispersion. Following the same behavior as niobates and tantalates where the compounds lower in the periodic table have lower dispersion, the tungstates have slightly lower dispersion than the molybdates. Among the uranyl compounds, meta-

torbernite $[\text{Cu}(\text{UO}_2\text{PO}_4)_2 \cdot 8 \text{H}_2\text{O}]$ and $\text{K}_2\text{UO}_2(\text{SO}_4)_2 \cdot 2 \text{H}_2\text{O}$ have high dispersion but this high dispersion may arise partially from the presence of water of hydration. β -uranophane, $\text{Ca}(\text{UO}_2)(\text{UOOH})\text{SiO}_4(\text{SiO}_3\text{OH}) \cdot 4 \text{H}_2\text{O}$, containing 4 H_2O has, however, normal dispersion.

Cs^+ and Ba^{2+} compounds seem to be conditionally “soft” ions. A few Cs compounds such as CsB_3O_5 , $\text{CsLiB}_6\text{O}_{10}$, $\text{CsAlSi}_2\text{O}_6 \cdot x \text{H}_2\text{O}$ and Cs_2SeO_4 , and Ba compounds such as BaO , $\text{BaBe}_2\text{Si}_2\text{O}_7$, $\text{BaAlSi}_2\text{O}_8$, and $\text{Ba}_2\text{MgGe}_2\text{O}_7$ have moderately high dispersion.

3.3.4. s^2 Ions

Wemple (1977) noted the reduced average energy gaps E_o for the s^2 ions Ti^+ , Pb^{2+} , and Bi^{3+} . We note in Table 7 that all the lone-pair cations lead to high dispersion. In general E_o values are low, varying from 5 to 9 eV. The highest dispersion is observed in TiCl , Na_2SbF_5 , PbMoO_4 , $\text{Pb}_5\text{Ge}_3\text{O}_{11}$, $\text{Pb}_2\text{Sc}_{0.5}\text{Ta}_{1.5}\text{O}_{6.5}$, Bi_2O_3 , and $\text{Bi}_2\text{Mo}_3\text{O}_{12}$. As for other compounds, the critical concentration of metal ion or combination of “soft” ions appears to be $\sim 10\%$. Both $\text{Ti}_2\text{Cd}_2(\text{SO}_4)_3$ ($A=84$) and PbB_4O_7 ($A=62$) with $\sim 10\%$ metal ions have reduced dispersion.

3.3.5. H_2O and Hydrates

DiDomenico and Wemple (1969) and Wemple (1977) noted the low values of the parameter E_d for both liquid H_2O and ice (9.5 and 8.6 eV, respectively). We find a slightly lower value for liquid H_2O of 7.3 eV. Table 8 shows that almost all hydrates have relatively low values of E_d , generally in the range 12–16 eV. Exceptions are diopatase $(\text{Cu}_6\text{Si}_6\text{O}_{18} \cdot 6 \text{H}_2\text{O})$, $K_2\text{UO}_2(\text{SO}_4)_2 \cdot 2 \text{H}_2\text{O}$, gypsum $(\text{CaSO}_4 \cdot 2 \text{H}_2\text{O})$, and afwillite $[\text{Ca}_3\text{Si}_2\text{O}_6(\text{OH})_2 \cdot 2 \text{H}_2\text{O}]$. The combination of moderate E_o and low E_d results in most hydrates having relatively high dispersion.

3.3.6. Summary of Effect of Electron Configuration and E_o and E_d on Dispersion

Table 9 summarizes the mean and maximum dispersion parameters A , E_o , and E_d along with their range for H_2O , hydrates and compounds containing the d^{10} ions Cu^+ , Zn^{2+} , As^{5+} , and I^{7+} , the s^2 ions As^{3+} , Sb^{3+} , Te^{4+} , I^{5+} , Ti^+ , Pb^{2+} , and Bi^{3+} , the p^6 ions Ti^{4+} , V^{5+} , Cr^{6+} , Mo^{6+} , Nb^{5+} , and Ta^{5+} , and the transition metal ions, Fe^{3+} , Cr^{3+} , Co^{2+} , Ni^{2+} , U^{4+} , and Eu^{2+} . High dispersion ($A = \sim 140$ – 250) is especially noticeable for H_2O and the ions Cu^+ , Zn^{2+} , I^{7+} , Sb^{3+} , V^{5+} , Cr^{6+} , Fe^{3+} , U^{4+} , and Eu^{2+} and for the compounds having a high concentration of H_2O and these ions: liquid H_2O , ice, CuCl , Cu_2O , ZnO , KIO_4 , Na_2SbF_5 , V_2O_5 , Fe_2O_3 , FeOOH , $\text{Fe}_2(\text{SO}_4)_3$, FeSO_4OH , $\text{Y}_3\text{Fe}_5\text{O}_{12}$, UO_2 , and β - Eu_2SiO_4 . In addition compounds containing combinations of these ions and others

associated with slightly lower A values have high dispersion: PbMoO_4 , Pb_2MoO_5 , $\text{Pb}_2\text{Sc}_{0.5}\text{Ta}_{1.5}\text{O}_{6.5}$, $\text{Pb}_5\text{V}_{2.5}\text{As}_{3}\text{O}_{12}\text{Cl}$, $\text{Bi}_2\text{Mo}_3\text{O}_{12}$, and $\text{Bi}_6\text{Mo}_2\text{O}_{15}$.

As noted in Sec. 3.3, dispersion is controlled by the combined effects of E_o and E_d . It is apparent from Fig. 2 that the low E_o values associated with these ions go a long way toward explaining the high dispersion values of compounds containing these ions. Note for example the low energy gaps associated with compounds containing Cu^+ , Te^{4+} , Bi^{3+} , Ti^{4+} , Fe^{3+} , U^{4+} , and Eu^{2+} .

However, it is clear that not only is low E_o necessary for high dispersion but also E_d must be reasonably low. Although the plot of A versus E_d shows a poorer fit to $1/E_o$ than $1/E_d$, the effects of E_d can be clearly seen in many cases. The effects of formal valence Z_a can be seen in low E_d and the relatively high dispersion of CuCl , Na_2SbF_5 , TiCl , and NiF_2 caused by lowered E_d and the effects of cation coordination can be observed in Cu_2O , ZnO , arsenates, vanadates, iodates, molybdates, and the ions As^{3+} , Sb^{3+} , Te^{4+} , and I^{5+} . As we have shown above, all hydrates have a relatively low E_d . The effects of water of hydration are apparent in the high dispersion of $\text{FeSO}_4\text{OH} \cdot 2 \text{H}_2\text{O}$, $\text{Fe}_2(\text{SO}_4)_3 \cdot 7 \text{H}_2\text{O}$, $\text{Cs}_2\text{Mg}(\text{CrO}_4)_2 \cdot 6 \text{H}_2\text{O}$, $\text{MgCrO}_4 \cdot 7 \text{H}_2\text{O}$, $\text{Pb}_3\text{Al}_2\text{CaSi}_{10}\text{O}_{27} \cdot 3 \text{H}_2\text{O}$, and $\text{Cu}(\text{UO}_2\text{PO}_4)_2 \cdot 8 \text{H}_2\text{O}$.

It is tempting to try to complement this rationalization of high dispersion values by correlating observed and calculated values of E_d with dispersion. Using the Wemple and DiDomenico (1971) scheme for calculating E_d for single ion compounds, it is not possible to calculate E_d for most compounds in Table 1 because of uncertainty over what to use for: (1) covalency; (2) N_e for s^2 and certain d^{10} compounds; and (3) cation coordination when there are two or more cations with differing N_c , i.e., YVO_4 , CaTiO_3 , CaMoO_4 , $\text{Y}_3\text{Fe}_5\text{O}_{12}$, and more complex compounds such as crystalline hydrates. Indeed, Wemple and DiDomenico noted that the scheelite compounds MMoO_4 with $\text{M}=\text{Ca}$, Sr , and Pb did not fit the scheme with $\beta=0.27$. On the other hand Wemple found that “anion radical” groups such as phosphates, sulfates, selenates, and chlorates resulted in good agreement between observed and calculated E_d but that a good fit was obtained for the iodates HIO_3 and LiIO_3 only by using $\beta=0.42$ – 0.44 . We have compared E_d values calculated using the properties of the anion groups such as BO_3^{3-} , BO_4^{5-} , PO_4^{3-} , VO_4^{3-} , SO_4^{2-} , SeO_4^{2-} , MoO_4^{2-} , and WO_4^{2-} and find that the counter ion almost always has an effect on E_d . These uncertainties added to those about N_e and N_c make it difficult to rely on calculated E_d values in the majority of multiion compounds. Thus, we make only the very general observation that the presence of H_2O , halide ions, and cations with low CNs such as Cu^+ , Zn^{2+} , As^{3+} , As^{5+} , Sb^{3+} , Te^{4+} , I^{5+} , V^{5+} , and Mo^{6+} sometimes contribute to lower E_d and therefore higher dispersion.

4. Acknowledgments

We gratefully acknowledge the use of the libraries at Universities in Bochum, Bremen, Mainz, and Boulder, Colorado for the literature search. We are especially indebted to Th. Armbruster, G. E. Jellison, and G. R. Rossman for critical reviews of the manuscript, to H. Fluck of the Gmelin Institute in Frankfort for the use of their library, E. Tillmanns for obtaining some of the earlier mineralogical references from the University of Vienna and Dr. U. Kalepky for use of the library of the Schott Glaswerke in Mainz. We are also grateful to H. Spetzler and J. Smyth for encouragement and support at CIRES/CU. We thank E. Eggers for the final formatting of the manuscript. Finally, one of us (R.D.S.) is indebted to the Humboldt Foundation for financial support.

8. Appendix 2. Alternative Forms of the Sellmeier Equation

The general form of the Sellmeier equation is usually given as

$$n^2 = 1 + \sum_j \frac{A_j \lambda^2}{\lambda^2 - \lambda_j^2}$$

with the wavelength λ of the incident light, and the wavelengths λ_j with the corresponding constants A_j representing the wavelengths of maximum absorption at several absorption bands. The refractive indices used in the current work are sufficiently approximated using a one-term Sellmeier equation with wavelengths λ far distant from the immediate region of the absorption band at λ_o , thus yielding

$$n^2 = 1 + \frac{A_o \lambda^2}{\lambda^2 - \lambda_o^2}.$$

Rearranging this equation gives

$$\frac{1}{n^2 - 1} = -\frac{\lambda_o^2}{A_o \lambda^2} + \frac{1}{A_o}$$

and finally

$$\frac{1}{n^2 - 1} = -\frac{A}{\lambda^2} + B$$

[Eq. (3a)] with $A = \lambda_o^2/A_o$ and $B = 1/A_o$ or $\lambda_o^2 = A/B$. The constant A_o is related to Eq. (3b) by the expression $E_d = A_o \cdot E_o$.
